

DIRECT RADIO-FREQUENCY DETECTION OF NUCLEOTIDE HYBRIDIZATION AT MICROELECTRODES

ABSTRACT OF THE DISCLOSURE

Radio-frequency (RF) excitation is used for direct detection of
5 hybridization events at microelectrodes with surface-attached DNA
oligomers. A homodyne reflectometer operates on a high frequency
carrier to detect the presence of a low-frequency modulation signal.
Without non-linearities in an interface, the modulation signal is not
impressed upon the carrier signal. As such, the reflectometer can
10 sensitively measure changes in dielectric properties without interference
from other sources of capacitance/resistance unrelated to the reaction at
the surface.
